Input-Output and Interrupts

Introduction

At the end of this lab you should be able to:

✦ Describe what interrupt vectors are and explain how they are used
✦ Describe two main methods of IO interrupt handling
✦ Explain the difference between the two main methods of IO interrupt handling
✦ Compare the merits of the two main methods of IO interrupt handling

Basic Theory

Computer systems use the interrupt mechanism as a means of responding to external events such as input and output operations. The CPU is momentarily interrupted just before executing the next instruction and is forced to execute the instructions of an interrupt handler. Once the interrupt handling is completed the CPU is returned back to executing the instruction it was about to execute before it was interrupted. The stack is used to store the CPU state such as the contents of registers and the return address when interrupted. These are then restored once the interrupt handler is exited.

Lab Exercises - Investigate and Explore

The lab investigations are a series of exercises that are designed to demonstrate the various aspects of IO interrupt handling.

Exercise 1 – Describe what interrupt vectors are and explain how they are used

In the compiler window, check only the boxes **Generate code**, **Enable optimizer** and **Redundant Code**. Enter the following source code and compile it:

```
program Vectors
    sub IntVect1 intr 1
        writeln("This is intr 1")
    end sub

    sub IntVect2 intr 2
        writeln("This is intr 2")
    end sub

    sub IntVect5 intr 5
        writeln("This is intr 5")
    end sub

    while true
    wend
end
```

In the compiled code window locate the subroutines *IntVect1, IntVect2* and *IntVect5*. Make a note of the starting addresses of these subroutines below:

Results:

Subroutine	Starting address
IntVect1	0
IntVect2	20
IntVect5	40

Next, do the following:
1. Load the code generated in CPU memory.
2. Click on the **INTERRUPTS…** button to view the **INTERRUPT VECTORS** window.
3. Make a note of the numbers displayed in text boxes next to **INT1**, **INT2** and **INT5**.

Note: The **INTERRUPT VECTORS** window in the simulator represents that part of the CPU hardware that stores the various interrupt routine addresses.

Results:

Interrupt	
INT1	0
INT2	20
INT5	40

Compare the two tables above and enter a brief comment on your observation in the space below:

เลขของที่อยู่เริ่มต้นของ subroutine
และตัวเลขที่แสดงใน INT1, INT2 และ INT5
เป็นเลขเดียวกัน

Now, follow the instructions below:

1. Click on the **INPUT OUTPUT…** button to view the console window.
2. Select **Stay on top** boxes both in the console and the interrupt vectors windows.
3. Reset the **Vectors** program and run it at the fastest speed.
4. While the program is running, click **TRIGGER** buttons in the interrupts window against **INT1**, **INT2** and **INT5** one after the other.
5. Observe the messages displayed on the console. Comment on your observations:

Tip: If you run the program at a slow pace (speed slider down), you should be able to see the effects of clicking on the **TRIGGER** buttons.

Comment on your observations in the space below:

โปรแกรมจะทำงานต่อเนื่องไปเรื่อย ๆ
โดยเมื่อคลิกปุ่ม trigger จะมีข้อความจาก subroutine แสดงออกมา
ทำให้โปรแกรมหลักหยุด กระโดดไปหาสิ่งที่ interrupt
แล้วค่อยกลับมาทำงานโปรแกรมหลักต่อ

Exercise 2 – Describe two main methods of interrupt handling

Enter the following source code in a new source editor and compile it.

```
program PolledInt
    var v integer

    v = 0
    writeln("Program Starting")
    while true
        read(nowait, v)
        for i = 1 to 100
            if v > 0 then
                break *
            end if
            write(".")
        next
    wend
    writeln("Program Ending")
end
```

Notes:

✦ The **nowait** keyword in the read statement makes sure the program is not suspended while waiting for an input.

✦ If there is no input, the value of the variable **v** will remain unchanged.

✦ The **break *** statement takes the program out of the outermost loop which in this case is the while loop.

So, now, briefly explain what the above program is doing:

- โปรแกรมจะ print "." ในขณะที่รอ input
- หากค่าที่ input เข้ามามากกว่า 0 โปรแกรมจะหยุดพิมพ์ "."
  จากนั้นจะแสดงข้อความ "Program Ending" และจบการทำงาน
- ถ้าโปรแกรม print "." ครบ 100 จุด โปรแกรมจะหยุดทำงาน

Next, follow the instructions below:

1. Load the code generated in CPU memory.
2. Set the speed of simulation to maximum.
3. Bring the console window up (use the **INPUT OUTPUT…** button).
4. Check the **Stay on top** check box on the Console.
5. Click in the **INPUT** box on the Console.
6. Start the simulation by clicking the CPU Simulator's **RUN** button. As soon as the **Program Starting** message is displayed on the Console, type any single character in the **INPUT** box of the Console. Wait until the program terminates.

Next, enter the following source code in a new source editor and compile it.

```
program VectoredInt
    var v integer

    sub InputInt intr 1
        read(nowait, v)
    end sub

    v = 0
    writeln("Program Starting")
    while true
        for i = 1 to 100
            if v > 0 then
                break *
            end if
            write(".")
        next
    wend
    writeln("Program Ending")
end
```

Briefly explain what the above program is doing (note where the read statement is in this case)

โปรแกรมทำงานเหมือนข้อที่แล้ว
ต่างกันที่หาก input เลขมากกว่า 0 โปรแกรมจะหยุดทำงาน

Load the code generated in CPU memory. Reset and run this code at the fastest speed. As soon as the **Program Starting** message is displayed on the Console, type any single character in the **INPUT** box of the Console. Wait until the program terminates.

Results:
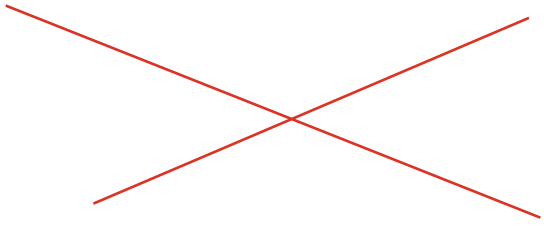

โปรแกรมแสดงผลว่า Program Ending

Exercise 3 – Explain the difference between polled and vectored interrupts

Based on your observation in the previous exercise, briefly explain the difference in the behaviors of the two programs, *PolledInt* and *VectoredInt,* with respect to the speed of response to input. Explain why this difference.

- RolledInt ช้ากว่า เพราะต้องรอให้โปรแกรมตรวจสอบ input ใหม่อย่างต่อเนื่อง
- VectoredInt เร็วกว่า เพราะสามารถขัดจังหวะโปรแกรมได้ทันทีเมื่อมี input เกิดขึ้น โดยไม่ต้องตรวจสอบ

Based on your observations in exercises 2, and looking at the table below, which interrupt handling method listed in the table, is more efficient (put an **X** against it):

Answer:

Interrupt method	Select the most efficient one
Polled Interrupt	
Vectored Interrupt	✗

Exercise 4 – Compare the merits of the two main methods of interrupt handling

1. Based on your observations above, suggest and briefly describe a reason where you would use the Polled Interrupt method in preference to the Vectored Interrupt method?

Polled Interrupt
- เหมาะสำหรับงานที่ไม่ได้ต้องการการตอบสนองทันที
- มีช่วงเวลาให้ตรวจสอบ input ของเรา

2. Very briefly describe where you would use the Vectored Interrupt method in preference to the Polled Interrupt?

Vectored Interrupt
- เหมาะสำหรับงานที่ต้องการการตอบสนองทันที เช่น งานที่มีความสำคัญสูง ระบบ Real-Time

****
